

# Vv156 Lecture 4

Dr Jing Liu

UM-SJTU Joint Institute

September 27, 2016

- Unlike for sequences, there are several types of limits for a function

$$y = f(x)$$

- We want to know the behaviour of  $f$  near a point  $x = a$  or near infinity, e.g.  
We may be interested in knowing the behaviour of average speed near  $t = 3$

$$\text{Average Speed} = \frac{\text{Distance travelled}}{\text{Time interval}} = \frac{s(t + \delta t) - s(t)}{\delta t}$$

- For an object that is dropped and falls straight down towards earth when the resistance of air is neglected, we have

$$s = \frac{1}{2}gt^2, \quad \text{where } g \approx 10\text{m/s}^2$$

$\delta t$	1.0000	0.5000	0.0100	0.0050	0.0001	0.00005
$s(3 + \delta t) - s(3)$	35.0000	16.2500	0.3005	0.1501	0.0030	0.0015
Average Speed	35.0000	32.5000	30.0500	30.0250	30.0005	30.0002

## Definition

The value  $L$  is the **limit** of  $f(x)$  as  $x$  approaches  $a$ ,

$$\lim_{x \rightarrow a} f(x) = L$$

if the values of  $f(x)$  can be made as close as we like to  $L$  by taking values of  $x$  sufficiently close to  $a$ , but not equal to  $a$ .

- There are two ways that  $x$  can approach  $a$ , from the left or from the right

$$\lim_{x \rightarrow a^-} f(x) = L = \lim_{x \rightarrow a^+} f(x)$$

0.5000	0.0100	0.0050	0.0001	0.00005	0.00005	0.0001	0.0050	0.0100	0.5000
13.7500	0.2995	0.1499	0.0030	0.0015	0.0015	0.0030	0.1501	0.3005	16.2500
27.5000	29.9500	29.9750	29.9995	29.9997	30.0002	30.0005	30.0250	30.0500	32.5000

- The two-sided limit exists if and only if the one-sided limits exist and are equal.

- For example, consider  $\lim_{x \rightarrow 0} \frac{|x|}{x}$

## Matlab

```
>> syms x; ezplot('abs(x)/x',[-1,1]);  
>> hold on; plot(0,1,'ro'); plot(0,-1,'ro'); hold off;  
>> xlabel('x'); ylabel('y');
```

- The limit concerns the value of **dependent variable**  $y$ ,  $y = f(x)$ , as the value of the **independent variable**  $x$  gets

closer and closer to  $a$  rather than the value of  $y$  at  $x = a$ .

- It is clear that

$$f(x = 2) = -2$$

$$\lim_{x \rightarrow 2} f(x) = 4$$

## Matlab

```
>> syms x;  
>> ezplot('x+2');  
>> hold on;  
>> plot(2,4, 'ro');  
>> plot(2,-2,'b.', 'MarkerSize', 15);  
>> hold off;  
>> xlabel('x'); ylabel('y');
```

- Limits that are infinite and limits at infinity, for example, consider the following
- Approaches  $\infty$  or  $-\infty$

$$\lim_{x \rightarrow \infty} \frac{x^2}{x^2 - 1} = 1$$

$$\lim_{x \rightarrow -\infty} \frac{x^2}{x^2 - 1} = 1$$

- Approaches to  $\infty$  or  $-\infty$

$$\lim_{x \rightarrow 1^-} \frac{x^2}{x^2 - 1} = -\infty$$

$$\lim_{x \rightarrow 1^+} \frac{x^2}{x^2 - 1} = \infty$$

$$\lim_{x \rightarrow -1^-} \frac{x^2}{x^2 - 1} = \infty$$

$$\lim_{x \rightarrow -1^+} \frac{x^2}{x^2 - 1} = -\infty$$

## Matlab

```
>> syms x
>> num = 2*power(x,2); denom = power(x,2) - 1;
>> f = num/denom;
>> ezplot(f,[-3 3])
>> xlabel('x'); ylabel('y');
```

## Limit Laws

Assume that  $\lim_{x \rightarrow a} f(x) = K$  and  $\lim_{x \rightarrow a} g(x) = L$ , and that  $c$  is constant,

- 1 The limit of a constant is the constant itself.

$$\lim_{x \rightarrow a} c = c$$

- 2 The limit of a sum/difference is the sum/difference of the limits.

$$\lim_{x \rightarrow a} [f(x) \pm g(x)] = \lim_{x \rightarrow a} f(x) \pm \lim_{x \rightarrow a} g(x) = K \pm L$$

- 3 The limit of a product is the product of the limits.

$$\lim_{x \rightarrow a} [f(x)g(x)] = \left[ \lim_{x \rightarrow a} f(x) \right] \left[ \lim_{x \rightarrow a} g(x) \right] = KL$$

- 4 The limit of a quotient is the quotient of the limits.

$$\lim_{x \rightarrow a} \left[ \frac{f(x)}{g(x)} \right] = \frac{\lim_{x \rightarrow a} f(x)}{\lim_{x \rightarrow a} g(x)} = \frac{K}{L}, \quad \text{provided } \lim_{x \rightarrow a} g(x) \neq 0$$

## Limit Laws

Assume that  $\lim_{x \rightarrow a} f(x) = K$  and  $\lim_{x \rightarrow a} g(x) = L$ , and that  $c$  is constant,

5 If  $f$  is a polynomial or a rational function and  $a$  is in the domain of  $f$ , then

$$\lim_{x \rightarrow a} f(x) = f(a)$$

6 If  $f(x) = g(x)$  for all  $x$  near  $a$ , possibly except at  $x = a$ , then

$$\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} g(x), \quad \text{provided the limits exist}$$

## The Squeeze Theorem

If  $g(x) \leq f(x) \leq h(x)$  when  $x$  is near  $a$ , except possibly at  $a$ , and if

$$\lim_{x \rightarrow a} g(x) = \lim_{x \rightarrow a} h(x) = L, \quad \text{then } \lim_{x \rightarrow a} f(x) = L$$

## Exercise

(a) Evaluate the following limits

$$\lim_{x \rightarrow 1} \frac{x^2 - 1}{x - 1}$$

$$\lim_{x \rightarrow 1} \frac{2x^2 + 6x}{x^2 - 9}$$

(b) Use the squeeze theorem to show  $\lim_{x \rightarrow 0} x \sin \frac{1}{x} = 0$

- The following precise definition of limit removes any vagueness in the definition.

### Epsilon-Delta definition of limit

Let  $f$  be a function defined on some open interval that contains the number  $a$ , except possibly at  $a$  itself. The value of  $L$  is the **limit** of  $f(x)$  as  $x$  approaches  $a$ ,

$$\lim_{x \rightarrow a} f(x) = L$$

if for every number  $\epsilon > 0$  there is a number  $\delta > 0$  such that

$$|f(x) - L| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta$$

$f(x)$  between  $L-\varepsilon$  and  $L+\varepsilon$  is guaranteed for the set of  $x$ .

- This precise definition of limit removes any vagueness, and thus can be used to prove or establish results or theorems regarding limits.
- For example, consider

$$\lim_{x \rightarrow -1} (x^2 + 3) = 4$$

- For every  $\epsilon > 0$ , we need to find  $\delta > 0$  (which depends on  $\epsilon$ ) such that

$$|f(x) - 4| < \epsilon \quad \text{if} \quad 0 < |x - (-1)| = |x + 1| < \delta$$

- Since  $\delta$  is the upper bound of  $|x + 1|$ , we need to know how  $|x + 1|$  behaves.
- Specifically, we need to find the upper bound in terms of  $\epsilon$ .
- This can be done by investigating what leads to  $|f(x) - 4| < \epsilon$

$$\begin{array}{lll}
 |f(x) - 4| < \epsilon & \text{if and only if} & |x^2 + 3 - 4| < \epsilon \\
 & \text{if and only if} & |x^2 - 1| < \epsilon \\
 & \text{if and only if} & |(x - 1)(x + 1)| < \epsilon \\
 & \text{if and only if} & |x - 1||x + 1| < \epsilon
 \end{array}$$

- So we have

$$|f(x) - 4| < \epsilon \quad \text{if and only if} \quad |x - 1||x + 1| < \epsilon$$

- We will now “replace” the term  $|x - 1|$  with an appropriate constant and keep the term  $|x + 1|$  since  $|x + 1|$  is what we are after.
- To do so, we will arbitrarily assume that  $\delta \leq 1$ . This is a valid assumption to make since, in general, once we find a  $\delta$  that works, all smaller values of  $\delta$  also work.

Based on this assumption, then

$$|x + 1| < \delta \leq 1 \implies |x + 1| < 1$$

$$\implies -1 < x + 1 < 1$$

$$\implies -2 < x < 0$$

$$\implies 1 < |x - 1| < 3$$

- Now if we combine  $|x - 1| < 3$  with the result

$$|f(x) - 4| < \epsilon \quad \text{if and only if} \quad |x - 1||x + 1| < \epsilon,$$

then we know

$$|f(x) - 4| < \epsilon \quad \text{if and only if} \quad (3)|x + 1| < \epsilon$$

- This means an upper bound of  $\frac{\epsilon}{3}$  for  $|x + 1|$  will guarantee

$$|f(x) - 4| < \epsilon, \quad \text{provided that } \delta \leq 1.$$

- Therefore choosing  $\delta = \min\{1, \frac{\epsilon}{3}\}$  will guarantee both assumptions made about  $\delta$  in the course of this proof are simultaneously taken into account, and will guarantee that

$$|f(x) - 4| < \epsilon \quad \text{if} \quad 0 < |x + 1| < \delta$$

for all  $\epsilon > 0$ .

- More importantly, the Epsilon-Delta definition is used to establish limit laws.
- For example, for the following limit laws:

1.  $\lim_{x \rightarrow a} c = c$
2.  $\lim_{x \rightarrow a} cf(x) = c \lim_{x \rightarrow a} f(x) = cK$ , where  $K = \lim_{x \rightarrow a} f(x)$ .

### Proof

- For the first part, let  $f(x)$  be the constant function, that is  $f(x) = c$ . We need to show that, for every number  $\epsilon > 0$  there is a number  $\delta > 0$  such that

$$|f(x) - c| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta$$

- The left inequality is always satisfied for any  $x$  since  $f(x) = c$ .

Thus for any  $\epsilon > 0$ , not only there is a number  $\delta > 0$  such that

$$|f(x) - c| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta$$

actually every  $\delta > 0$  is fine.

## Proof

- For the second part, if  $c = 0$  then  $cf(x) = 0$ , and  $\lim_{x \rightarrow a} [0f(x)] = \lim_{x \rightarrow a} 0$ .

It reduces to a special case of limit law 1., with  $c = 0$ . Therefore we know 2. is true for  $c = 0$  and so we can assume that  $c \neq 0$  for the remainder of this proof.

- Suppose  $\epsilon > 0$ , then  $\frac{\epsilon}{|c|} > 0$ . Because  $\lim_{x \rightarrow a} f(x) = K$  by the precise definition of the limit there exists a  $\delta_1 > 0$  such that,

$$|f(x) - K| < \frac{\epsilon}{|c|} \quad \text{if} \quad 0 < |x - a| < \delta_1$$

Now suppose  $\delta = \delta_1$  is a valid choice, to finish we need to show that

$$|cf(x) - cK| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta$$

Assume that  $0 < |x - a| < \delta$ , then  $0 < |x - a| < \delta_1$ , which means

$$|f(x) - K| < \frac{\epsilon}{|c|} \implies |c||f(x) - K| < \epsilon \implies |cf(x) - cK| < \epsilon \quad \square$$

## The Squeeze Theorem

If  $g(x) \leq f(x) \leq h(x)$  when  $x$  is near  $a$ , except possibly at  $a$ , and if

$$\lim_{x \rightarrow a} g(x) = \lim_{x \rightarrow a} h(x) = L, \quad \text{then} \quad \lim_{x \rightarrow a} f(x) = L$$

### Proof

- Suppose that  $g(x) \leq f(x) \leq h(x)$  for all  $x \neq a$  in near  $a$  and also that

$$\lim_{x \rightarrow a} g(x) = L = \lim_{x \rightarrow a} h(x) = L$$

- Let  $\epsilon > 0$ . Since

$$\lim_{x \rightarrow a} g(x) = L$$

- there is  $\delta_g > 0$  so that

$$|g(x) - L| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta_g$$

- Notice that this implies that

$$-\epsilon < g(x) - L < \epsilon \implies g(x) > L - \epsilon$$

## Proof

- Similarly, since

$$\lim_{x \rightarrow a} h(x) = L$$

- there is  $\delta_h > 0$  so that

$$|h(x) - L| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta_h$$

and this implies that  $h(x) < L + \epsilon$ .

- Let  $\delta = \min\{\delta_g, \delta_h\}$  and  $0 < |x - a| < \delta$ . Then

$$L - \epsilon < g(x) \leq f(x) \leq h(x) < L + \epsilon$$

$$L - \epsilon < f(x) < L + \epsilon$$

- Hence,  $|f(x) - L| < \epsilon$ . Since  $\epsilon > 0$  is arbitrary,  $\lim_{x \rightarrow a} f(x) = L$ . □

- We can definite limit at infinity and infinite limit precisely. For example,

### Definition

Let  $f$  be function defined on some open interval that contains the number  $a$ , except possibly at  $a$  itself. Then the limit of  $f(x)$  approaches infinity, written as,

$$\lim_{x \rightarrow a} f(x) = \infty \quad \text{or} \quad f(x) \rightarrow \infty \quad \text{as} \quad x \rightarrow a$$

if for every number  $M > 0$  there exists a number  $\delta > 0$  such that

$$f(x) > M \quad \text{if} \quad 0 < |x - a| < \delta$$

### Definition

Let  $f$  be function defined on some open interval  $(a, \infty)$ . Then the limit of  $f(x)$

$$\lim_{x \rightarrow \infty} f(x) = L \quad \text{or} \quad f(x) \rightarrow L \quad \text{as} \quad x \rightarrow \infty$$

if for every number  $\epsilon > 0$  there exists a number  $M \in (a, \infty)$  such that

$$|f(x) - L| < \epsilon \quad \text{if} \quad x > M$$

- Many of our limits laws can be modified to accommodate infinity. For example,

### Theorem

Suppose  $f(x)$  and  $g(x)$  are two functions such that

$$\lim_{x \rightarrow a} f(x) = \infty \quad \lim_{x \rightarrow a} g(x) = L$$

1. The limit of the sum/difference is infinity

$$\lim_{x \rightarrow a} [f(x) \pm g(x)] = \infty$$

2. The limit of the product is infinity if  $L > 0$  and negative infinity if  $L < 0$

$$\lim_{x \rightarrow a} [f(x)g(x)] = \pm\infty$$

3. The limit of the quotient is infinity if  $L > 0$  and negative infinity if  $L < 0$

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \pm\infty \quad \text{and} \quad \lim_{x \rightarrow a} \frac{g(x)}{f(x)} = 0$$

## Proof

- For  $M > 0$ , we know there exists  $\delta_f$  such that if  $0 < |x - a| < \delta_f$ , we have

$$f(x) > \frac{2M}{L}$$

- We also know that there exists  $\delta_g$  such that if  $0 < |x - a| < \delta_g$ , we have

$$0 < |g(x) - L| < \frac{L}{2} \implies \frac{L}{2} < g(x) < \frac{3L}{2}$$

- Now let  $\delta = \min\{\delta_f, \delta_g\}$ , so if  $0 < |x - a| < \delta$  we know from the above,

$$f(x) > \frac{2M}{L} \quad \text{and} \quad g(x) > \frac{L}{2}$$

- This gives us

$$f(x)g(x) > \left(\frac{2M}{L}\right) \left(\frac{L}{2}\right) = M \quad \square$$

- All the limit laws hold when the limits are taken as  $x \rightarrow \infty$  instead of  $x \rightarrow a$ .

## Theorem

If  $r$  is a positive rational number, then  $\lim_{x \rightarrow \infty} \frac{1}{x^r} = 0$

## Proof

- For every  $\epsilon > 0$ , we need to show that there exists a number  $M$  such that

$$\left| \frac{1}{x^r} - 0 \right| < \epsilon \quad \text{when } x > M$$

- We know the root  $\sqrt[r]{\frac{1}{\epsilon}}$  will exist since  $\epsilon$  is positive, if we let  $x > M = \sqrt[r]{\frac{1}{\epsilon}}$ , then

$$x > \sqrt[r]{\frac{1}{\epsilon}} \implies x^r > \frac{1}{\epsilon} \implies \frac{1}{x^r} < \epsilon \implies \left| \frac{1}{x^r} - 0 \right| < \epsilon \quad \square$$

## Theorem

If  $p(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0$  is a polynomial of degree  $n$ , then

$$\lim_{x \rightarrow \infty} p(x) = \lim_{x \rightarrow \infty} a_n x^n$$

## Exercise

(a) Find  $\lim_{x \rightarrow \infty} \frac{x^2 + 5x + 1}{2x^2 - 10}$

## Theorem

The limit of a rational function as  $x \rightarrow \infty$  is the limit of the quotient of the terms of highest degree in the numerator and the denominator as  $x \rightarrow \infty$ .

## Exercise

(b) Find  $\lim_{x \rightarrow \infty} \frac{3x^2 + 1}{4x^3 + 2x + 1}$
